SANDOZ

TFM PROPOSAL

The extractor

Problem Statement

Critical data related to pharmaceutical products used in our processes is sourced from multiple external websites in an unstructured and inconsistent format, leading to data inaccuracies, manual rework, and downstream process inefficiencies.

Proposed Approach

To address this challenge, we propose developing an AI-powered scrapper and extractor that would help us get and structure in the right way the information we need to run our processes. The bot will:

- **Download data** related to pharmaceutical products from different websites like emea, fda ...
- **Extract from the documents** the information we need to run our business processes
- **Structure** it in a way that we have in our systems
- **Provide a summary** of where the data came from and the exact pages so that human validation can happen

This solution aims to move us to a less manual data entry in our systems and improve the overall data quality avoiding issues on downstream processes

Technical tools

The project will utilize LLMs in combination with Python and relevant libraries to scrape/download/connect to apis and generate the data that we need.
